**Ring:** - A system  $(R, +, \cdot)$  containing a set  $R$  and two binary operations called addition and multiplication is said to be a ring if this system satisfies the following conditions :-

- (1)  $(R, +)$  is an abelian group.
- (2)  $(a \cdot b) \cdot c = a \cdot (b \cdot c) \forall a, b, c \in R$

That is associative law is satisfied w.r.t multiplication

- (3) (i)  $a \cdot (b + c) = a \cdot b + a \cdot c \forall a, b, c \in R$
- (ii)  $(b + c) \cdot a = b \cdot a + c \cdot a \forall a, b, c \in R$

**Note 1:-** Since we have taken two binary operations ‘ + ’ and ‘  $\cdot$  ’, so closure property are naturally satisfied w.r.t both of the binary operations.

**Note 2:-** If there is no chance of confusion then in place of writing  $(R, +, \cdot)$  we shall write simply  $R$  to mean a ring.

**Commutative Ring**-- ring  $R$  is said to be commutative

if  $a \cdot b = b \cdot a, \forall a, b \in R$ .

**Ring with unity:** - A ring  $R$  is said to be with unity if  $\exists$  an element  $1$  in  $R$  such that

$1 \cdot a = a \cdot 1 = a$  for every  $a \in R$ .

**A Commutative Ring with unity:** - It means a ring  $R$  which is commutative and has a unity.

**Inversible element or a unit:** - An element  $a$  in a ring  $R$  is called invertible (or a unit) if  $\exists$  an element  $b \in R$  such that  $a \cdot b = b \cdot a = 1$ . In this situation we write  $b = a^{-1}$  and we speak that  $b$  is the multiplicative inverse of  $a$ .

**Division Ring:** - A ring  $R$  with unity is called a division ring if non zero elements of  $R$  form a group w.r.t multiplication clearly if non zero elements of  $R$  must have multiplicative inverse.

## Some examples of Ring:-

- (1) The set of integers w.r.t usual '+' and '.' is a commutative ring with unity
- (2) The set of even integers is a commutative ring without unit element w.r.t ordinary '+' and '.'
- (3) The set of all real valued functions defined over the closed interval  $[0,1]$  forms a ring

w.r.t '+' and '.' defined as follows:-

$$(f+g)(x)=f(x)+g(x)$$

$$(f.g)(x)=f(g(x)) .$$

- (4) The set  $M$  of all  $2 \times 2$  square matrices whose elements are real numbers a ring w.r.t addition and multiplication of matrices.

**Zero –Divisor:-** Let  $R$  be a commutative ring A non zero element  $a$  of  $R$  is called a zero divisor if we have another non zero element  $b$  in  $R$  such that  $ab = 0$ .

**Proper Divisors of Zero :-** If  $a.b = 0$  and  $a \neq 0$  ,  $b \neq 0$  for  $a, b \in R$  then,  $a$  is called proper left zero divisor and  $b$  is called proper right zero divisor if we take them together they are said to be proper divisors of zero.

**Integral Domain:** - A commutative ring  $R$  with unity is called an integral domain if  $R$  has no zero divisors.

That is if  $ab = 0$  in  $R$  then either  $a=0$  or  $b=0$ .

That is the product of non zero elements in  $R$  is non zero.

**Example 1:-** The ring of integers is an integral domain w.r.t '+' and '.'.

**Example 2:-** The set  $E$  of all even integers with 0 is a commutative ring w.r.t usual '+' and '.'. But it is not an integral domain as  $1 \notin E$  for multiplication.

**Example 3:-** The ring  $I/(6)$  of residue class modulo 6 is a commutative ring with unity but it is not integral domain

**Left Ideal:** - A non empty subset  $I$  of a ring is called a left ideal of  $R$  if

$$(i) a, b \in I \Rightarrow a - b \in I$$

$$(ii) a \in I, r \in R \Rightarrow ra \in I$$

**Right Ideal:** - A non empty subset  $I$  of  $R$  is called a right ideal of  $R$  if

(i)  $a, b \in I \Rightarrow a - b \in I$

(ii)  $a \in I, r \in R \Rightarrow ar \in I$

**Ideal:** - A subset  $I$  of a ring  $R$  is called simply ideal if it is both left and right ideals.

**Maximal Ideal:** - Let  $M$  be an ideal of a ring  $R$  such that  $M \neq R$ , then  $M$  is called Maximal ideal of  $R$  if whenever  $A$  is an ideal of  $R$  such that  $M \subseteq A \subseteq R$  then either  $A = M$  or  $A = R$ .

NOTE: - A ring may have more than one maximal ideal.

**Prime Ideal:** - An ideal  $P$  of a ring  $R$  is called a Prime Ideal if

$ab \in P \Rightarrow a \in P$  or  $b \in P$ .

**EXAMPLE 1:**  $\{0\}$  in the ring  $Z$  of integers is a prime ideal as  $ab \in \{0\}$

$\Rightarrow ab = 0 \Rightarrow a = 0$  or  $b = 0 \Rightarrow a \in \{0\}$  or  $b \in \{0\}$ .

**EXAMPLE 2:**  $H_4 = \{4n : n \in Z, Z \text{ is the set of integers}\}$  then  $H_4$  is a maximal ideal but not a prime ideal.

Observation: Let  $(E, +, \cdot)$  be a ring of even integers.

By question  $H_4 = \{4n : n \text{ is an integer}\}$ .

Then  $H_4$  is an ideal of  $E$  and as  $2 \notin H_4, H_4 \neq E$ .

Let  $A$  be any ideal of  $E$  such that  $H_4 \subseteq A \subseteq E$ .

Sufficient to show that,  $A = H_4$  or  $A = E$ .

If  $H_4 \neq A$ , we have  $A = E$

Since  $H_4 \subset A, \exists$  some  $x \in A$  such that  $x \notin H_4$

By division algorithm, we can write that  $x = 4q + r$  where  $0 < r < 4$ .

Then clearly  $r \neq 0$  otherwise  $x = 4q \Rightarrow x \in H_4$  which goes against assumption.

Now  $r = 1, 3 \Rightarrow x$  is odd  $\Rightarrow x$  does not belong to  $E \Rightarrow$

So  $r$  must be equal to 2

Thus  $x = 4q + 2 \Rightarrow 2 = x - 4q \in A$

Thus as  $x \in A, 4q \in H_4 \subseteq A \Rightarrow x - 4q \in A$ .

$2 \in A \Rightarrow$  multiples of 2 are in A (by the definition of ideal)

$\Rightarrow E \subseteq A$ . But  $A \subseteq E$ . Hence  $A = E$

Thus  $H_4 = \{ 4n : n \text{ is an integer} \}$  is a maximal ideal in E.

[3]

However  $H_4$  is not prime ideal as  $2 \times 2 = 4 \in H_4$  but  $2 \notin H_4$

Thus  $H_4$  is maximal ideal but not a prime ideal

**Principal Ideal:** - An ideal M of a ring R is said to be principal ideal if it is generated by a single element of S. That is, if  $a \in S$  then  $S = \{a\}$ .

**NOTE 1 :-** A ring R with unity is itself called the unit ideal because the ideal generated by 1 i.e,  $\{1\}$  is the ring R itself as  $r \cdot 1 = r, \forall r \in R$ .

**NOTE 2 :-** The ideal generated by the zero element of R i.e,  $\{0\}$  is called null ideal.

**Divisibility in an integral Domain:** - Let a be a non zero element of a commutative ring R.

Then a divides  $b \in R, \exists$  an element  $c \in R$  such that  $b = ca$ .

We generally use the symbols  $a/b$  to represent the fact that “ a divides b ”. Here a is called a factor of b.

Clearly every non zero element of R is a divisor of its zero element.

**Theorem 1:-** If R is a commutative ring, then

(i)  $a/b$  and  $b/c \Rightarrow a/c$

(ii)  $a/b$  and  $a/c \Rightarrow a/(b+c)$

(iii)  $a/b \Rightarrow a/bx, \forall x \in R$ .

(iv) if R has unity then  $1/x \forall x \in R$  and if a is a unit then  $a/x \forall x \in R$ .

**Proof:-**

(i)  $a/b \Rightarrow b = a m, \text{ for some } m \in R$

and  $b/c \Rightarrow c = b n, \text{ for some } n \in R$

Thus  $c = b n = (a m) n = a (m n)$

$\Rightarrow a/c$  as  $m, n \in R \Rightarrow m n \in R$ .

(ii)  $a/b \Rightarrow b = a m$ , for  $m \in R$  and

$a/c \Rightarrow c = a n$ , for  $n \in R$

Thus  $b + c = a m + a n = a (m+n)$

$\Rightarrow a/(b+c)$  as  $m, n \in R \Rightarrow (m+n) \in R$

(iii)  $a/b \Rightarrow b = a n$ , for some  $n \in R$

$\Rightarrow b x = a n x$ , for all  $n \in R$

$\Rightarrow a/b x, \forall n x \in R$ .

(iv) it can be easily verified.

**Greatest common divisor or H.C.F:-** Let  $R$  be a commutative ring and  $a, b \in R$ . Then an element  $d \in R$  is called greatest common divisor (G.C.D.) or highest common factor (H.C.F.) of  $a$  and  $b$  if

(i)  $d/a$  and  $d/b$

(ii) whenever  $c/a, c/b$  then  $c/d$

In this case we write  $d = \text{g.c.d}(a, b)$ . It is also denoted by  $(a, b)$

**Least common multiple or L.C.M:-** Let  $R$  be a commutative ring. A non zero Element  $l \in R$  is called least common multiple (L.C.M) of two non zero elements  $a, b \in R$ . if

(i)  $a/l$  and  $b/l$

(ii) if  $a/x, b/x$  then  $l/x$

We denote  $l$  by  $\text{l.c.m}(a, b) = [a, b]$ .

**Associates:** - Let  $R$  be a commutative ring with unity. Then any two elements  $a, b \in R$  are called associates if  $b = ua$  for some unit  $u \in R$ . In this case we also write  $a \sim b$ .

**Principal ideal Domain:-** An integral domain  $R$  with unity is called a principal ideal domain (P.I.D) if every ideal of  $R$  is a principal ideal.

**Principal ideal ring :-** A commutative ring with unity is called a principal ideal ring if every ideal of  $R$  is a principal ideal.

**Prime element :-** Let  $R$  be a commutative ring with unity an element  $p \in R$  is called prime element if:

(i)  $p \neq 0$ ,  $p$  is not a unit

(ii) for any  $a, b, c \in R$  if  $p \mid ab$  then  $p \mid a$  and  $p \mid b$

**Irreducible element** :- An element  $p$  of a commutative ring  $R$  with unity is called an irreducible element if

(i)  $p \neq 0$ ,  $p$  is not a unit

(ii) whenever  $p = ab$ , then one of  $a$  and  $b$  must be a unit .

**Theorem 2:-** Let

- (i)  $R$  be an integral domain ( I. D)
- (ii)  $a, b \in R$  be non zero elements

Then  $a/b$  and  $b/a$  iff  $a$  and  $b$  are associates.

**Proof:-** By question,  $R$  is an integral domain with unity and  $a, b \in R$ ,  $a, b$  are non zero.

Suppose  $a/b$  and  $b/a$

Since  $a/b \Rightarrow b = x a$ , for some  $x \in R$

$b/a \Rightarrow a = y b$  for some  $y \in R$

Thus  $b = x a = x (y b) \Rightarrow b - x (y b) = 0 \Rightarrow b ( 1 - x y) = 0 \Rightarrow 1 - x y = 0 \Rightarrow x y = 1$

$\Rightarrow y$  is a unit in  $R$  and  $a = y b$ .

Conversely let  $a, b$  are associates :

As we know that  $\exists$  a unit  $u$  such that  $a = b u \Rightarrow b/a$  and  $a/b$ .

**Theorem3:-** Let  $R$  be an integral domain (I. D) with unity then

$d_1 = \text{g.c.d} (a,b)$  in  $R$  then  $d_2$  is also a g.c.d  $(a,b)$  iff  $d_1 = d_2$  are associates.

**Proof:-** Let  $d_1, d_2$  both are g.c.d  $(a,b)$

Then as we know that, we can write  $d_1/a$ ,  $d_1/b$  and  $d_2/a$ ,  $d_2/b$ .

So by definition we get  $d_1/d_2$  from which  $d_1$  and  $d_2$  are associates.

Conversely : let  $d_1 = \text{g.c.d} (a,b)$  and  $d_2$  be an associates of  $d_1$

then  $u d_2 = d_1$ , for some unit  $u$ .

$\Rightarrow d_2/d_1$  and as  $d_1/a$ ,  $d_1/b$ , we find  $d_2/a$ ,  $d_2/b$ .

Let  $x/a$ ,  $x/b$  then  $x/d_1$  as  $d_1$  is g.c.d  $(a,b)$ .

Also as  $d_2 = d_1 u^{-1}$  so  $d_1/d_2 \Rightarrow x/d_2$ .

Thus  $d_2 = \text{g.c.d}(a,b)$ .

**Theorem 4:-** In an integral domain if there exists a lowest common multiple (L.C.M) of any two elements, then it is unique apart from the distinction between the associates.

**Proof:-** Let  $a, b$  be any two non zero elements of an integral domain  $D$ .

Also let L.C.M of  $a$  and  $b$  exist.

if possible let for a moment that  $l_1$  and  $l_2$  are two L.C.M of  $a$  and  $b$  then

We see that: if  $l_1$  is the L.C.M of  $a$  and  $b$  then we have  $a/l_1$  and  $b/l_1$

Similarly if  $l_2$  is the L.C.M of  $a$  and  $b$  then we have  $a/l_2$  and  $b/l_2$

but then  $l_1/l_2$  and Similarly  $l_2/l_1$

Thus  $l_1/l_2$  and  $l_2/l_1 \Rightarrow$  that  $l_1$  and  $l_2$  are associates.

**Theorem 5:-** Each pair of elements surely has a least common multiple in a principal ideal domain.

**Proof:-** Let  $a, b$  be any two non zero elements of a principal ideal domain (P.I. D.)  $D$ .

Also let  $(a)$  and  $(b)$  stand for principal ideal of  $D$  generated by  $a$  and  $b$  respectively.

Clearly  $(a) \cap (b)$  is an ideal of  $D$  [since intersection of two ideals is again an ideal]

Also  $(a) \cap (b)$  is principal ideal but then there will exist an element  $l$  in  $D$

such that  $(a) \cap (b) = (l)$ .

It remains to show that  $l$  is the L.C.M.

For, since  $(a) \cap (b) = (l) \Rightarrow (l) \subset (a)$  and  $(l) \subset (b)$

$\Rightarrow l \in (a)$  and  $l \in (b) \Rightarrow l = a x_1$  and  $l = b x_2$  for some  $x_1, x_2 \in D$ .

$\Rightarrow a/l$  and  $b/l$

$\Rightarrow l$  is a common multiple of  $a$  and  $b$

Now if  $m$  is a common multiple of  $a$  and  $b$ , then  $a/m$  and  $b/m$ .

Thus  $m = a y_1$  and  $m = b y_2$ , for some  $y_1, y_2 \in D$ .

Now  $x \in (m) \Rightarrow x = m z_1$ , for some  $z_1 \in D$

$$\Rightarrow x = (a y_1) z_1 \Rightarrow x = a(y_1 z_1), y_1, z_1 \in D \Rightarrow x \in (a)$$

$$\text{That is } x \in (m) \Rightarrow x \in (a) \Rightarrow (m) \subseteq (a)$$

In a similar style we can establish that  $(m) \subseteq (b)$

$$\Rightarrow (m) \subseteq (a) \cap (b)$$

$$\Rightarrow (m) \subseteq (l)$$

$$\Rightarrow m \in (l) \Rightarrow m = ly, \text{ for some } y \in D \Rightarrow l/m$$

Thus  $a/l, b/l$  and if  $m/a$  and  $m/b$ , then  $l/m$

Thus  $l$  is the least common multiple of  $a$  and  $b$ .

**Theorem 6:-** In every principal ideal domain (P.I. D.) each pair of non zero elements surely has a greatest common divisor.

**Proof:-** Let  $a, b$  be any two non zero elements of a principal ideal domain  $D$ .

Also let  $(a)$  and  $(b)$  be principal ideal generated by  $a$  and  $b$  respectively.

As we know that  $(a) + (b)$  is an ideal in  $D$  and every ideal of  $D$  is principal.

Thus  $(a) + (b)$  is principal ideal but then there exists  $d \in D$ ,

$$\text{Such that } (a) + (b) = (d)$$

Our problem is to establish that  $d = \text{greatest common divisor } (a,b)$ .

$$\text{For, since } (a) + (b) = (d) \Rightarrow (a) \subset (d), (b) \subset (d)$$

$$\text{Now } (a) \subset (d) \Rightarrow a = d x_1, \text{ for some } x_1 \in D \Rightarrow d/a$$

$$\text{Also } (b) \subset (d) \Rightarrow b = d x_2, \text{ for some } x_2 \in D \Rightarrow d/b.$$

So  $d$  is the common divisor of  $a$  and  $b$ .

If possible, let for a moment that  $c$  is also a common divisor of  $a$  and  $b$ .

$$\text{So that } c/a \text{ and } c/b \Rightarrow a = c y_1 \text{ and } b = c y_2, \text{ for some } y_1, y_2 \in D.$$

$$\text{Thus } x \in (a) \Rightarrow x = a z_1 \text{ for some } z_1 \in D.$$

$$\Rightarrow x = (c y_1) z_1 = c (y_1 z_1), \text{ where } y_1 z_1 \in D$$

$$\Rightarrow x \in (c) \Rightarrow (a) \subset (c)$$

Similarly it can be shown that  $(b) \subset (c)$

Therefore  $(a) \subset (c)$  and  $(b) \subset (c) \Rightarrow (a) + (b) \subset (c)$

$\Rightarrow (d) \subset (c) \Rightarrow d \in (c) \Rightarrow d = cz$ , for some  $z \in D \Rightarrow c/d$ .

Hence  $d/a$  and  $d/b$  and whenever  $c/a, c/b$  then  $c/d$

Therefore  $d = \text{greatest common divisor}(a,b)$ ,

**Theorem 7:-** In a principal ideal domain (P.I. D.), an element is prime if and only if it is irreducible.

**Proof:-** Let  $D$  be a principal domain. Let  $p \in D$  be a prime element

To prove that if  $p = ab$  then  $a$  or  $b$  is a unit.

For, let  $p = ab$  then  $p/ab \Rightarrow p/a$  or  $p/b$ , where  $p$  is prime.

If  $p/a$  then  $a = px$ , for some  $x$ . Then  $p = ab = (px)b \Rightarrow p(1 - xb) = 0$

But  $p \neq 0$  so  $1 - xb = 0 \Rightarrow xb = 1 \Rightarrow b$  is a unit.

Similarly it can be shown that if  $p/b$  then ' $a$ ' will be a unit

Conversely: let  $p$  is irreducible element and  $p/ab$

To show  $p/a$  or  $p/b$

if possible let  $p/a$ .

Also  $p$  and  $a$  are members of a P.I. D. So by a theorem they must have a greatest common divisor. Let this G.C.D be  $d$ .

To show  $d$  is a unit.

For,  $d/p$  and  $d/a \Rightarrow$  there exists  $u$  and  $v$  such that  $p = du, a = dv$

If  $d$  is not a unit, then as  $p$  is irreducible and  $p = du, u$  will be a unit.

$\Rightarrow u^{-1}$  exists  $\Rightarrow pu^{-1} = d$

Thus  $a = pu^{-1}v \Rightarrow p/a$  which is a contradiction

Thus  $d$  is a unit.

$d$  is g.c.d. so  $d$  can be expressed as  $d = \lambda a + \mu p$  which gives us

$$d d^{-1} = d^{-1} \lambda a + d^{-1} \mu p \Rightarrow b \cdot 1 = \lambda d^{-1} a b + \mu d^{-1} b p$$

But  $p/ab, p/ \mu d^{-1}bp$ .

Therefore,  $p/ ( ab \lambda d^{-1} + \mu d^{-1}bp ) \Rightarrow p/b$ . ,,

**Euclidean Rings or Euclidean Domain:** - Let  $R$  be an integral domain then  $R$  is called Euclidean ring (or Euclidean Domain) if for every non zero element  $a \in R$  there exists a non negative integers  $d(a)$  such that :

- (i) For all non zero elements  $a, b \in R$ ,  $d(a) \leq d(ab)$  [or  $d(b) \leq d(ab)$ ]
- (ii) For each  $a, b \in R$  with  $b \neq 0$ , there exists  $q, r \in R$  such that  $a = bq + r$  where either  $r = 0$  or  $d(r) < d(b)$

**Note 1 :-** The above property (ii) is known as division algorithm.

$d$  is known as Euclidean norm function. We do not assign a value to  $d(0)$

**Example of Euclidean Rings:-** The ring  $Z$  of all integers is an Euclidean ring.

**Solution:-** Let  $Z =$  the set of all integers and

$$N = \text{set of non-negative integers}$$

We define a mapping  $d : z \rightarrow N$  given by  $d(a) = |a|, \forall a \in Z$  and  $a \neq 0$ .

Since  $|a|$  is non-negative as  $a \neq 0$ .

It means for every non zero integer  $a$ ,  $d(a)$  is non-negative integer of  $Z$ .

We now consider :

- (i) If  $a, b$  are any two non zero elements of  $I$  then  $d(a) = |ab| = |a| |b| \geq |a|$  ( since  $|b| \geq 1, \forall$  non zero  $b \in Z$  )  
 $\Rightarrow d(ab) \geq d(a) \Rightarrow d(a) \leq d(ab) \forall a, b \in Z$ .
- (ii) If  $a, b$  are any two non zero elements of  $Z$ , then by algorithm  $\exists q, r \in Z$  such that  $a = bq + r$  where  $0 \leq r < |b|$ ,  
 So that  $0 \leq r < |b| \Rightarrow$  either  $r = 0$  or  $0 < r < |b|$   
 $\Rightarrow$  either  $r = 0$  or  $|r| < |b|$  ( since  $0 < r \Rightarrow |r| = r$  )  
 $\Rightarrow$  either  $r = 0$  or  $d(r) < d(b)$

So we find that the mapping  $d$  is a Euclidean valuation on  $Z$  and accordingly  $Z$  is a Euclidean ring.

**Theorem 8:-** Every Euclidean ring is a principal ideal ring.

**Proof:-** Let  $R$  be an Euclidean ring and  $S$  be an arbitrary ideal of  $R$ .

To show that  $S$  is a principal ideal

If  $S = (0)$  i.e,  $S$  is generated by 0 then  $S$  is a principal ideal.

If  $S \neq (0)$  then there must exist a non zero element say  $b \in S$  i.e,  $b \neq 0$

Let  $d(b)$  be minimal so we cannot get  $c$  in  $S$  such that  $d(c) < d(b)$

We show that  $S = (b)$  that is  $S$  is generated by  $b$ .

Clearly for any  $a \in S \exists q$  and  $r$  in  $R$  such that

$A = bq + r$  where either  $r = 0$  or  $d(r) < d(b)$

As  $S$  is an ideal so,

$q \in R$  and  $b \in S \Rightarrow bq \in S$

Also  $q \in R$  and  $bq \in S \Rightarrow a - bq \in S \Rightarrow r \in S$

But we have either  $r = 0$  or  $d(r) < d(b)$  contradict that  $d(b)$  is generated by  $b$ .

i.e,  $S = (b)$  so that  $S$  is a principal ideal.

Also  $S$  is an arbitrary ideal in  $R$ .

Thus  $R$  is a principal ideal ring.

Hence  $a = bq \Rightarrow$  that every element of  $S$  can be expressed as a multiple of  $b$ .

Thus  $S = (b) \Rightarrow S$  is a principal ideal.

Hence  $R$  is a principal ideal ring.

**Theorem 9:-** An Euclidean ring possesses a unit element.

**Proof:-** Let  $R$  be an Euclidean ring. But we know that every Euclidean ring is a principal ideal ring.

Clearly  $R$  is itself an ideal of  $R$  so it is principal ideal.

Let  $R = (u_0)$  for  $u_0 \in R$ .

So every element in  $R$  is a multiple of  $u_0$ .

In particular  $u_0 = u_0 c$ , for some  $c$  in  $R$ .

Let  $a$  be any element of  $R$ , then  $a = x u_0$ , for some  $x \in R$ .

So  $ac = (x u_0) c = x (u_0 c)$ . Also  $R$  is a commutative ring.

Thus  $ac = a = c a$ ,  $\forall a \in R$ .

Thus  $c$  is unit element of  $R$ .

**Theorem 10 :-** The necessary and sufficient that the non zero element  $a$  in the Euclidean ring  $R$  is a unit is that  $d(a) = d(1)$ .

**Proof:-** Let  $R$  be an Euclidean ring.

Also let  $a$  be a non zero element of  $R$  and  $a$  is a unit then by definition of Euclidean ring.

$$d(a) = d(1 \cdot a) \geq d(1) \text{ or } d(a) \geq d(1) \text{ -----(1)}$$

$$a \text{ is unit in } R \Rightarrow a^{-1} \text{ exists in } R \text{ then } 1 = a a^{-1} \Rightarrow d(1) = d(a a^{-1}) \geq d(a)$$

$$\Rightarrow d(1) \geq d(a) \text{ -----(2)}$$

Thus from (1) and (2)  $d(a) = d(1)$

Conversely: let  $d(a) = d(1)$ . To show  $a$  is a unit in  $R$ .

If possible, let for a moment that  $a$  is not unit in  $R$

Then by a theorem  $d(1, a) > d(1) \Rightarrow d(a) > d(1)$  which is a contradiction

$\therefore a$  is unit in  $R$ .

**Theorem 11 (Unique Factorization theorem ) :-** Statement let  $R$  be a Euclidean ring and  $a \neq 0$  a non unit in  $R$ . Suppose

$a = p_1 p_2 \dots p_m = q_1 q_2 \dots q_n$ , where each  $p_i$  and  $q_i$  are prime elements of  $R$  then  $m = n$  and each  $p_i$  ( $1 \leq i \leq m$ ) is an associate of some  $q_i$  ( $1 \leq i \leq n$ ) and each  $q_i$  is an associative of some  $p_i$ .

**Proof:-** Since given  $a = p_1 p_2 \dots p_m = q_1 q_2 \dots q_n$  -----(1)

Also  $p_1 \mid p_1 p_2 \dots p_m \Rightarrow p_1 \mid q_1 q_2 \dots q_n \Rightarrow p_1$  must divide at least one of

$q_1, q_2, \dots, q_n$  ( since  $R$  is commutative)

By left cancellation law, we have

$$p_2 p_3 \dots p_m = u_1 q_2 q_3 \dots q_n \text{ -----(2)}$$

We repeat the above argument on (2) with  $p_2, p_3$  and so on

If  $m < n$  then after  $m$  steps, the left side becomes 1 and the right side reduces to a product of some units in  $R$  and certain numbers of  $q_j$ 's. But  $q_j$ 's are not units in  $R$ , so that the product of some units and some  $q_j$ 's cannot be equal to 1.

This shows that  $m < n$ .

Thus we obtain  $m \geq n$  -----(3)

Now interchanging the role of  $q_i$ 's and  $q_j$ 's, we get  $n \geq m$  -----(4)

Thus from (3) and (4), we obtain  $m = n$ .

Clearly the above process shows the fact that every  $p_i$  has some  $p_j$  as an associate and conversely.

**Theorem 12 :** An ideal  $S$  of the Euclidean ring  $R$  is maximal if and only if  $S$  is generated by some prime element of  $R$ .

**Proof:-** Let  $a$  be an element of an Euclidean ring and  $S = (a)$  be an ideal generated by  $a$ .

Also every Euclidean ring  $\Rightarrow$  principal ideal ring .

So  $S$  is a principal ideal. Let  $S$  is maximal ideal.

We have show that  $a$  is a prime element in  $R$  .

We claim that  $a$  is a prime element.

If not  $a$  is a composite number but then  $a = bc$  -----(1)

Where  $b, c$  are non zero units in  $R$ .

(1) implies that  $b|a$  then for some  $x \in R, ax \in (a)$ , then

$$ax = (bc)x = b(x) \in (b)$$

Thus  $(a) \subset (b) \subset R \Rightarrow S \subset (b) \subset R \Rightarrow$  either  $S = (b)$  or  $S = R$  (since  $S$  is maximal)

When  $S = (b)$  then  $(a) = (b) \Rightarrow (b) \subseteq (a) \Rightarrow b \in (a) \Rightarrow b = ay$  for some  $y \in R$ .

$$\Leftrightarrow b = (bc)y \Rightarrow b = b(cy) \Rightarrow b - b(cy) = 0 \Rightarrow b(1 - cy) = 0 \text{ but } b \neq 0$$

$$\Leftrightarrow 1 - cy = 0 \Rightarrow cy = 1 \Rightarrow c \text{ is a unit in } R \text{ which is a contradiction.}$$

Thus supposing that  $a$  is not prime we arrived at a contradiction .

However if  $S = R$  then  $(a) = R \Rightarrow 1 \in (a) \Rightarrow 1 = az$  for some  $z \in R \Rightarrow a$  is a unit in  $R$ , which contradicts the fact that  $a$  is not a unit in  $R$ .

Thus letting  $a$  not to be a prime number we arrived at a contradiction .

Thus our supposition was wrong .

Therefore  $a$  is prime element in  $R$  .

Conversely : Let  $S = (a)$  and  $a$  is prime element in  $R$  .

To show  $S$  is maximal.

For , let  $T$  be an ideal of  $R$  such that  $S \subset T \subset R$  .

Since every Euclidean ring is a principal ideal ring so  $R$  is principal ideal ring so  $T$  is principal ideal.

Let  $T = (b)$  , for  $b \in R$  .

But  $S \subset T \Rightarrow (a) \subset (b) \Rightarrow a = bx$  for some  $x \in R$ .

- $\Rightarrow b$  is either a unit in  $R$  or an associate of  $a$
- $\Rightarrow$  either  $(b) = R$  or  $(b) = (a)$
- $\Rightarrow$  either  $T = R$  or  $T = S$
- $\Rightarrow S$  is maximal ideal of  $R$ .

## EXERCISES

**Problem 1:-** Give an example to show that it is possible to have more than one g.c.d for the same pair of elements.

**Solution:-** Consider the ring  $R = \{ 0, 1, 2, \dots, 7 \}$  modulo 8

If there is no chance of confusion then by ordinary sign of multiplication ' $\times$ ' we shall mean a modified form of multiplication on the set of remainders.

Thus  $2 \times 3 = 6$  then  $2|6$

$2 \times 2 = 4$  then  $2|4$

Again , if  $c|4$  ,  $c|6$  than  $c|6 - 4 \Rightarrow c|2$

Thus g.c.d  $(4,6) = 2$  -----(1)

Also  $6 = 6 \times 1$

$$4 = 6 \times 6$$

So we find  $6|6$  and  $6|4$

Now  $c|6, c|4$

Then as  $c|6$ , we get  $\text{g.c.d}(4,6) = 6$  -----(2)

Thus from (1) and (2) it is possible to have more than one g.c.d for the same pair of elements.

**Problem 2:-** Verify whether in the ring  $E$  of even integers 4 and 6 have a g.c.d or not ?

**Solution :** The only possibility that 2 is not a g.c.d of 4, 6 as 2 does not divide 6 in  $E$ .

In fact  $6 = 2 \cdot 3$  but  $3 \notin E$ .

**Problem 3:-** Let  $R$  be an integral domain with unity and  $a, b \in R$  be non zero elements such that  $a|b$  and  $b|a$ , then  $a$  and  $b$  are associates.

**Solution :** Since  $a|b \Rightarrow b = xa$  for some  $x, y \in R$

$$b|a \Rightarrow a = yb$$

Thus  $b = xa = x(yb) \Rightarrow b(1 - xy) = 0 \Rightarrow 1 - xy = 0$  (as  $b \neq 0$ )

$\Rightarrow y$  is a unit in  $R$  and  $a = yb$ .

**Problem 4:-** Construct an example of Euclidean domain.

**Solution :** We consider the integral domain  $(\mathbb{Z}, +, \cdot)$  of integers.

For any non zero integer  $a$  in  $\mathbb{Z}$ , we define  $d(a) = |a|$  then  $d(a)$  is non negative integer.

Again, let  $a, b \in \mathbb{Z}$  be any two non zero elements,

Then  $d(a) = |a|, d(ab) = |ab| = |a| |b|$

$\therefore d(a) \leq d(ab)$  [ since  $|a| \leq |a| \cdot |b|$  ]

Again  $a, b \in \mathbb{Z}$  ( $a, b \neq 0$ )

Suppose  $b > 0$  then it is possible to write  $a = tb + r$  where  $0 \leq r < b, t, r \in \mathbb{Z}$

If  $r \neq 0$  then  $r < b \Rightarrow |r| < |b| \Rightarrow d(r) < d(b)$ .

Also if  $b < 0$  then  $(-b) > 0$  so there exists  $t, r \in \mathbb{Z}$  such that

$a = (-b)t + r$  where  $0 \leq r < -b$

or,  $a = (-t)b + r$ .

If  $r \neq 0$ ,  $r < -b \Rightarrow |r| < |b| \Rightarrow d(r) < d(b)$

Thus the system  $(\mathbb{Z}, +, \cdot)$  is a Euclidean domain.

**Problem 5:-** Show that in a P.I.D every non zero prime ideal is maximal .

**Solution :** Let  $P = (p)$ ,  $p \neq 0$  be a non zero prime ideal in a P.I.D  $R$ .

Let  $P \subseteq Q = (q) \subseteq R$  then  $p \in P \subseteq Q = (q) \Rightarrow p = qr \Rightarrow qr \in P$ .

$\Rightarrow q \in P$  or  $r \in P$ .

If  $q \in P$  then all multiples of  $q$  are in  $P \Rightarrow Q \subseteq P$ .

Thus  $Q = P$ .

If  $r \in P$  then  $r = pt \Rightarrow r = qrt \Rightarrow r(1-qt) = 0 \Rightarrow 1 = qt$  ( $r \neq 0$ )

But  $q \in Q$ ,  $t \in R \Rightarrow qt \in Q \Rightarrow 1 \in Q \Rightarrow Q = R$  .

**Problem 6:-** Show that an element  $x$  in a Euclidean domain is a unit if and only if  $d(x) = d(1)$

**Solution :** Let  $d(x) = d(1)$ ; to show  $x$  is a unit.

Let for a moment  $x$  is not a unit then by a theorem  $d(1) < d(1 \cdot x)$

That is  $d(1) < d(x)$  which is a contradiction.

Thus  $x$  is a unit.

Conversely : Let  $x$  is a unit, to prove  $d(x) = d(1)$

But  $x$  is a unit in  $R$  then there exists  $y$  in  $R$  such that  $xy = 1$

Since by definition  $d(x) \leq d(xy) \Rightarrow d(x) \leq d(1)$  -----(1)

Also  $d(1) \leq d(1 \cdot x) \Rightarrow d(1) \leq d(x)$  -----(2)

Thus from (1) and (2)

$$d(x) = d(1)$$

Hence the problem.

**Problem 7:-** Show by an example that it is possible to find two elements  $a, b$  in a Euclidean domain such that  $d(a) = d(b)$  but  $a, b$  are not associates.

**Solution :** Consider  $D = \{ a + ib : a, b \in \mathbb{Z} \}$ . Also let  $d(a + ib) = a^2 + b^2$

Then  $D$  is a Euclidean domain .

Here  $d(2 + 3i) = 13 = d(2 - 3i)$  but  $2 + 3i$  and  $2 - 3i$  are not associates.

We note here that units of  $D$  are  $\pm 1$  ,  $\pm i$  and thus an associate of  $2 + 3i$  can be

$$(2 + 3i) 1, (2 + 3i) (-1), (2 + 3i) i, (2 + 3i) (-i)$$

That is  $2 + 3i, -2 - 3i, 2i - 3, 3 - 2i,$

Which are all different from  $2 + 3i$ .

**Problem 8:-** Show that whenever  $a, b$  are relatively prime in a Euclidean domain  $R$ , then  $\text{g.c.d}(a, b) = 1$ .

**Solution :** Since by a theorem any associate of a g.c.d is a g.c.d.

Also since 1 is associate of any unit.

So 1 will be an associate of  $d = \text{g.c.d}(a, b) = \text{a unit} \Rightarrow 1 = \text{g.c.d}(a, b)$ .

**Problem 9:-** Find all the units of  $\mathbb{Z}(\sqrt{-5})$

**Solution :** Assume that  $a + \sqrt{-5} b$  is unit in  $\mathbb{Z}(\sqrt{-5})$

Then  $(a + \sqrt{-5} b)(c + \sqrt{-5} d) = 1 + \sqrt{-5} \cdot 0$ , for some  $c, d \in \mathbb{Z}$

Therefore  $(a - \sqrt{-5} b)(c - \sqrt{-5} d) = 1 \Rightarrow a^2 + 5b^2 = 1 \Rightarrow a = \pm 1, b = 0$

Thus  $a + \sqrt{-5} b = \pm 1$  are the units.

**Problem 10:-** Consider the ring  $\mathbb{Z}(\sqrt{-5}) = \{ a + \sqrt{-5} b : a, b \in \mathbb{Z} \}$

Under the operation defined by

$$\{ a + \sqrt{-5} b \} + \{ c + \sqrt{-5} d \} = (a + c) + \sqrt{-5} (b + d)$$

$$\text{and } (a + \sqrt{-5} b) \cdot (c + \sqrt{-5} d) = (ac - 5bd) + \sqrt{-5} (ad + bc)$$

Then (1)  $\sqrt{-5}$  is a prime element

(2) 3 is an irreducible element which is not prime

**Solution :** Since  $\sqrt{-5} \neq 0$

If it is not a unit then  $\exists a + \sqrt{-5} b$  such that

$\sqrt{-5}(a + \sqrt{-5} b) = 1 \Rightarrow \sqrt{-5} = 1 + 5b$  is not possible because R.H.S is an integer where as it is not an integer.

Let  $\sqrt{-5}$  divides  $(a + \sqrt{-5} b)(c + \sqrt{-5} d)$  then  $\exists (x + \sqrt{-5} y)$

Such that  $\sqrt{-5}(x + \sqrt{-5} y) = (a + \sqrt{-5} b)(c + \sqrt{-5} d)$

On comparison we get  $-5y = ac - 5bd \Rightarrow 5(bd - y) = ac \Rightarrow 5 \mid ac$ .

But 5 being a prime number, therefore either  $5 \mid a$  or  $5 \mid c$

If  $5 \mid a$  then  $(\sqrt{-5})(\sqrt{-5}) \mid a \Rightarrow \sqrt{-5} \mid a \Rightarrow \sqrt{-5} \mid (a + b\sqrt{-5})$

Similarly, if  $5 \mid c$ , then  $\sqrt{-5} \mid c + \sqrt{-5} d$ .

Thus  $\sqrt{-5}$  is a prime element.

Thus first part is done.

For the (2) part:-

Since  $3 = (a + \sqrt{-5} b)(c + \sqrt{-5} d)$ ,  $a, b, c, d \in \mathbb{Z}$

$$\Rightarrow \bar{3} = (a - \sqrt{-5} b)(c - \sqrt{-5} d) \Rightarrow 3 \cdot \bar{3} = (a^2 + 5b^2)(c^2 + 5d^2)$$

$$\Rightarrow 9 = (a^2 + 5b^2)(c^2 + 5d^2) \Rightarrow a^2 + 5b^2 = 1, 3 \text{ or } 9$$

Thus  $a^2 + 5b^2 = 3$  is not possible as  $a, b \in \mathbb{Z}$ .

If  $a^2 + 5b^2 = 1$  then  $a = \pm 1$  and  $b = 0$

If  $a^2 + 5b^2 = 9$ , then  $a^2 + 5d^2 = 1$ , then  $c = \pm 1$  and  $d = 0$

Thus, if  $a^2 + 5b^2 = 1$  then  $a + \sqrt{-5} b = \pm 1$ , which is a unit and if

$a^2 + 5b^2 = 9$ , then  $c + \sqrt{-5} d = \pm 1$ , which is also a unit.

Thus, 3 is an irreducible element of  $\mathbb{Z}(\sqrt{-5})$

Further, we have  $(2 + \sqrt{-5})(2 - \sqrt{-5}) = 9$  so  $3 \mid (2 + \sqrt{-5})(2 - \sqrt{-5})$

We show here that it does not divide anyone of these

Suppose  $3 \mid (2 + \sqrt{-5})$  in  $\mathbb{Z}(\sqrt{-5})$

Then  $(2 + \sqrt{-5}) = 3(a + \sqrt{-5} b)$ ,  $a, b \in \mathbb{Z}$ .

$$2 - \sqrt{-5} = 3(a - \sqrt{-5} b) \Rightarrow 9 = 9(a^2 + 5b^2) \Rightarrow 1 = a^2 + 5b^2 \text{ i.e., } a = \pm 1, b = 0$$

$2 + \sqrt{-5} = \pm 3$  which is not possible.

Thus  $3 \nmid (2 + \sqrt{-5})$

Similarly we can show that  $3 \nmid (2 - \sqrt{-5})$

Thus 3 is not a prime element of  $Z(\sqrt{-5})$ .

**Problem 11:-** An example of a prime element but not a irreducible.

**Solution :** Let us consider a ring  $Z_6 = \{ 0, 1, 2, 3, 4, 5 \} \text{ mod } 6$

Then 2 is a prime element in  $Z_6$  but is not irreducible. 2 is in fact non zero , non unit.

Let  $2 \mid a \times b$  ( here  $\times$  is modified sign of multiplication on the set of remainders )

Since  $ab = 6q + a \times b$  for some q and as  $2 \mid 6q, 2 \mid a \times b$ , we find  $2 \mid ab$ .

$$\Rightarrow 2 \mid a \text{ or } 2 \mid b \Rightarrow 2 \mid a \text{ or } 2 \mid b \in Z_6.$$

Thus 2 is prime element.

Again as  $2 \times 4 = 2$ , where neither 2 nor 4 is a unit.

We find 2 is not irreducible.
